

Chapter 1 : CakePhp Interview Question Answer

CakePHP is an open-source free web framework written in PHP scripting Language for rapid web blog.quintoapp.comP follows the model-view-controller (MVC) approach and modeled after the concepts of Ruby on Rails, and distributed under the MIT License.

A variable declared inside a function without any storage class specification, is by default an automatic variable. They are created when a function is called and are destroyed automatically when the function exits. Automatic variables can also be called local variables because they are local to a function. By default they are assigned garbage value by the compiler. The register variable functionality is same as auto storage class except that storage of variable is in register instead of memory. Register variable has faster access than normal variable. Frequently used variables are kept in register. Only few variables can be placed inside register depends on the register of processors. The Register variable does not guarantee the storage of variable in register it depends on the availability of register. We can never get the address of such variables. This storage class is used to declare static variables which are popularly used while writing programs in C language. Static variables have a property of preserving their value even after they are out of their scope! Hence, static variables preserve the value of their last use in their scope. So we can say that they are initialized only once and exist till the termination of the program. Thus, no new memory is allocated because they are not re-declared. Their scope is local to the function to which they were defined. Global static variables can be accessed anywhere in the program. By default, they are assigned the value 0 by the compiler. The extern keyword is used before a variable to inform the compiler that this variable is declared somewhere else. The extern declaration does not allocate storage for variables. When you have multiple files and you define a global variable or function, which will also be used in other files, then extern will be used in another file to provide the reference of defined variable or function. Just for understanding, extern is used to declare a global variable or function in another file. The extern modifier is most commonly used when there are two or more files sharing the same global variables or functions as explained below. When this program is executed, it produces the following result?

Important CakePHP Interview Questions with best Answers. These questions are are frequently asked in interview and very helpful for freshers.

TimeHelper What is a Behavior? Behaviors are used to change the way models behaves and enforcing model to act as something else. What is the difference between Component, Helper, Behavior?
